(Sub-)millimeter optical constants of silicates and water ice

Tuesday, 12 June 2018 14:14 (1 minute)

We provide new temperature-dependent optical constants of silicate glasses, silicate minerals, and crystalline and amorphous water ice, in the sub-millimeter spectral range, for silicate glasses up to a wavelength of 4 mm. We compare these optical constants to literature data, such as the “astronomical silicate” and commonly used extrapolations of the water-ice opacity. We discuss physical reasons of the strong temperature dependence of the absorptivity seen in the data, and consequences for the contribution of these materials to the sub-millimeter emission of cosmic dust.

Consider for a poster?

Yes

Primary authors: Dr MUTSCHKE, Harald (Astronomical Institute and University-Observatory Jena); MOHR, Pierre; HÄSSNER, Denny

Co-authors: Dr LEWEN, Frank (1. Phys. Institut, Universität Köln); Prof. BLUM, Jürgen (IGEP, TU Braunschweig); POTAPOV, Alexey (Max Planck Institute for Astronomy); Dr GUNDLACH, Bastian (IGEP, TU Braunschweig); DRESSLER, Tim (1. Phys. Institut, Univ. Köln)

Presenter: Dr MUTSCHKE, Harald (Astronomical Institute and University-Observatory Jena)

Session Classification: Poster Presentations

Track Classification: What is dust?
