Introduction

- Association of masers with star forming regions is well known.
- Common maser molecules: SiO, OH, NH₃, H₂O, H₂CO, CH₃OH
- Numerous surveys have been done in the past to catalog Galactic masers (see eg. work by Jim Caswell and co-workers).
- Main use of masers: diagnostic of physical conditions, kinematics (proper motion studies), magnetic fields, Galactic structure.
- Advantages: Masers "probe" small regions of molecular gas; are bright and can easily be detected/monitored with single dish telescopes.
- Difficulties: Non-LTE physics involved. Population inversion possible over a range of physical conditions.

Time domain study of masers

- Has been known that masers associated with high-mass star forming regions are variable.
- Discovery of periodic varying CH₃OH masers in G9.62+0.20E (Goedhart et al, 2003).
- Currently ~ 25 periodic methanol maser sources out of a total of ~ 950 detected methanol masers
- Periods range from 29 days to more than 500 days
- A variety of light curves suggests more than one underlying periodic mechanism (orbital motion, stellar pulsation)
- Recently also periodic OH masers discovered (Goedhart et al, 2019, Seidu et al, 2019, in preparation). One periodic CH₃OH + H₂CO source also known.
- ► Class II methanol masers: Lifetime ~ (25 40) kyr

ABSTRACT

We present (sub)millimeter imaging at 0'5 resolution of the massive star-forming region G385 93-0.03 acquired in multiple epocks at 2 and 3 months following the recent flaring of its 6.7 GHz CH₃OH maser emission. Using SMA and ALMA, we have discovered 14 new Class II CH₃OH maser lines ranging in frequency from 199 to 361 GHz, which originate mostly from $v_i=1$ torsionally-excited transitions. The masers are associated with the brightest continuum source (MMI), which also hosts a line-rich hot core. The masers present a consistent curvilinear spatial velocity pattern that wraps around MMI, suggestive of a coherent physical structure. In contrast, the thermal lines exhibit a linear velocity gradient that bisects MMI but at progressive position angles that appear to be a function of either increasing temperature or decreasing optical depth. The maser spectral profiles have evolved significantly over a one month period, and the intensities have all dropped by factors of 3.0 to 7.2, with the sole $v_i=2$ transition showing the largest change. A small area of maser emission from only the highest excitation lines closest to MMI has completely disappeared. There are seven additional dust continuum sources found in the protocluster, including another hot molecular core (MM3). We do not find the optical background by the protocluster, including another hot molecular core (MM3). We

Take home message

- Although interpreting maser emission might be difficult, masers do reveal important physical activity in high-mass star forming regions that otherwise would not be detected.
- Dedicated maser monitoring necessary to catch such events.
