Probing nuclear structure in heavy-ion collisions with cumulants of transverse momentum fluctuations

Friday 31 March 2023 15:40 (1h 50m)

The structure of atomic nuclei can be described by a multipole expansion of the parton distribution function. Most nuclies generally have intrinsic deformation, where the quadrupole moment carries the most significant contribution. The shape of a quadrupole deformed nuclies is described by the deformation strength β_2 , and an axial symmetry component γ . In ultra-relativistic heavy-ion collision, the nuclear shape directly affects the energy density of the created Quark-Gluon-Plasma (QGP) and the radial flow blast. We present a direct measurement of cumulants of transverse momentum fluctuation as a fine probe for accessing initial stage properties of deformed nuclies. Using the AMPT model Xe-Xe collisions at $\sqrt{s_{NN}} = 5.44\text{TeV}$ are simulated with different quadrupole moments defined by both strength β_2 , and triaxiality γ . The results show the higher-order cumulant of transverse momentum fluctuation to have a sensitive response to both β_2 and γ .
