## Ultra-high-energy neutrinos to look for super-heavy dark matter inside Earth

*Friday 14 March 2025 16:05 (1h 55m)*

As the Earth travels across the Milky Way, it passes through the galactic halo of dark matter particles. Occasionally a dark matter particle could interact with the contents of the earth, scattering it to a lower energy, which can lead to it becoming gravitationally trapped inside the Earth. If these dark matter particles are self-annihilating, or decay, one possible final state product will be neutrinos, which would lead to a flux of neutrinos at the surface of the earth, coming from dark matter, thus enabling indirect dark matter detection. The work focuses on the specific case of super-heavy dark matter in the mass range  $1e7$  GeV to  $1e11$  GeV, and explores the possibility of detecting ultra-high-energy neutrinos in the planned IceCube-Gen2 detector, in the hopes that data in the next 10–15 years can either discover or set new limits on dark matter.

### Field of study

Astrophysics

### Supervisor

Mauricio Bustamante

**Author:** VOSS JACOBSEN, Johannes
