

Galactic flows and the formation of stellar clusters

Ian Bonnell

Romas Smilgys, Clare Dobbs, Rowan Smith,
Thomas Maschberger, Nick Moeckel,
John MacLachlin, Jim Dale, Kenny Wood,
Diego Falceta-Goncalves, Matthew Bate, Paul Clark

Early Life of Stellar Clusters, 2014

GMC scale star formation

- $10^4 M_{\text{sun}}$ in 10 pc

SPH : 1.5×10^7 particles

- Forms > 2500 stars

in 6×10^5 years

$\sim 1600 M_{\text{sun}}$ ($\sim 0.003 M_{\text{sun}} \text{ yr}^{-1}$)

Mass resolution $\sim 0.02 M_{\text{sun}}$

Sink radius: 200 AU

No MHD, feedback

Initial conditions:

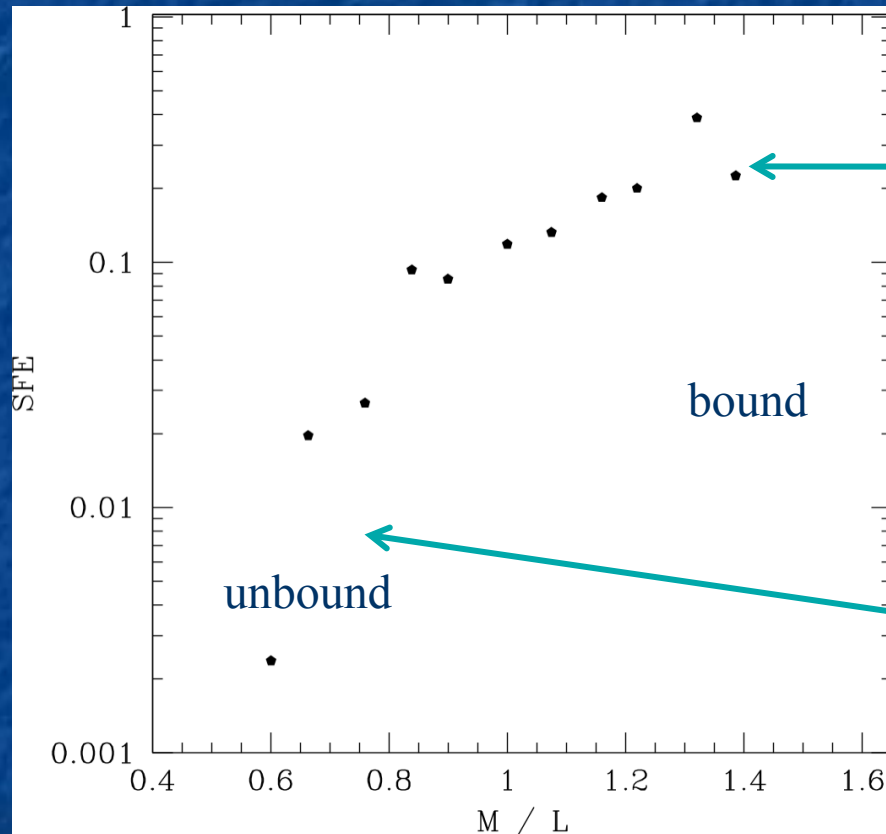

Bound (top) and

Unbound (bottom)

SF efficiencies and clustering

- **Bound** conditions produce **stellar clusters**

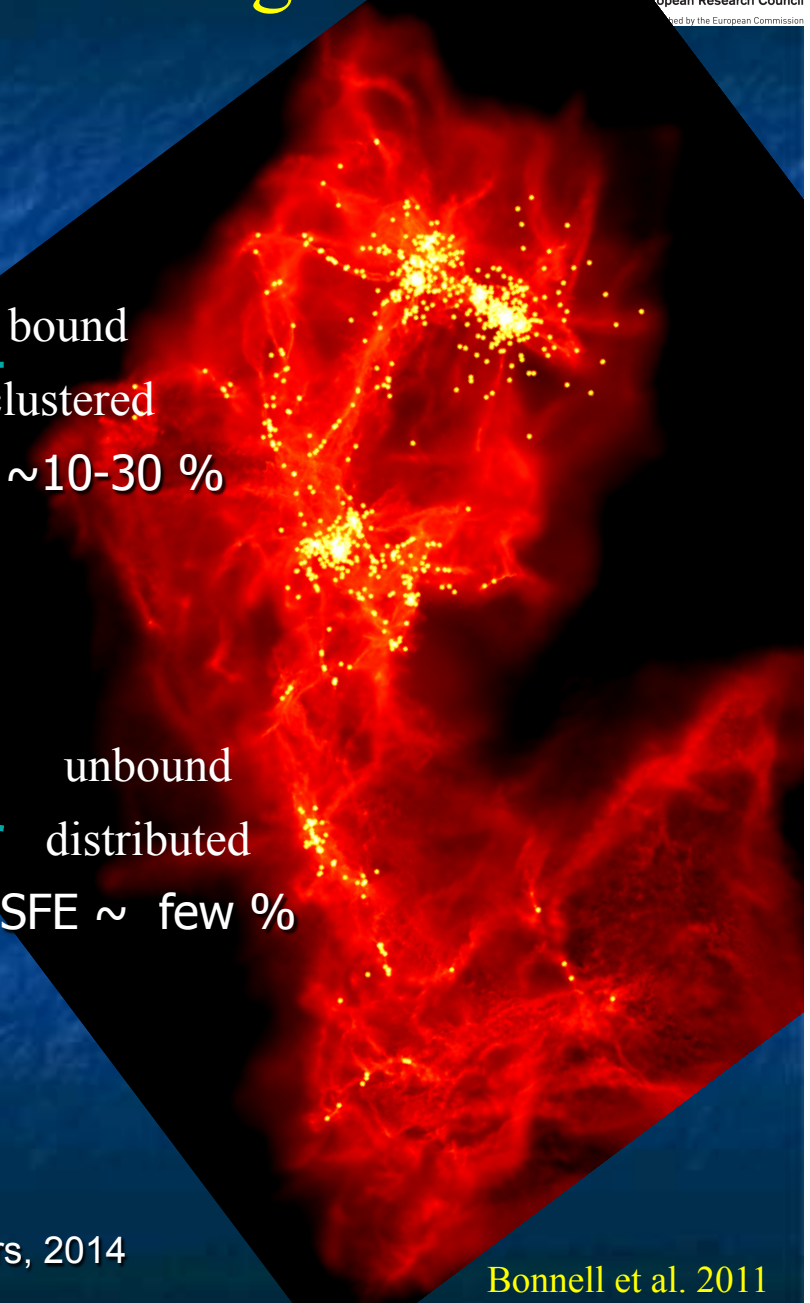

bound
clustered
SFE ~10-30 %

unbound
distributed
SFE ~ few %

- **Unbound** regions produce
 - Low SF efficiencies
 - See Clark et al 2008

Early Life of Stellar Clusters, 2014

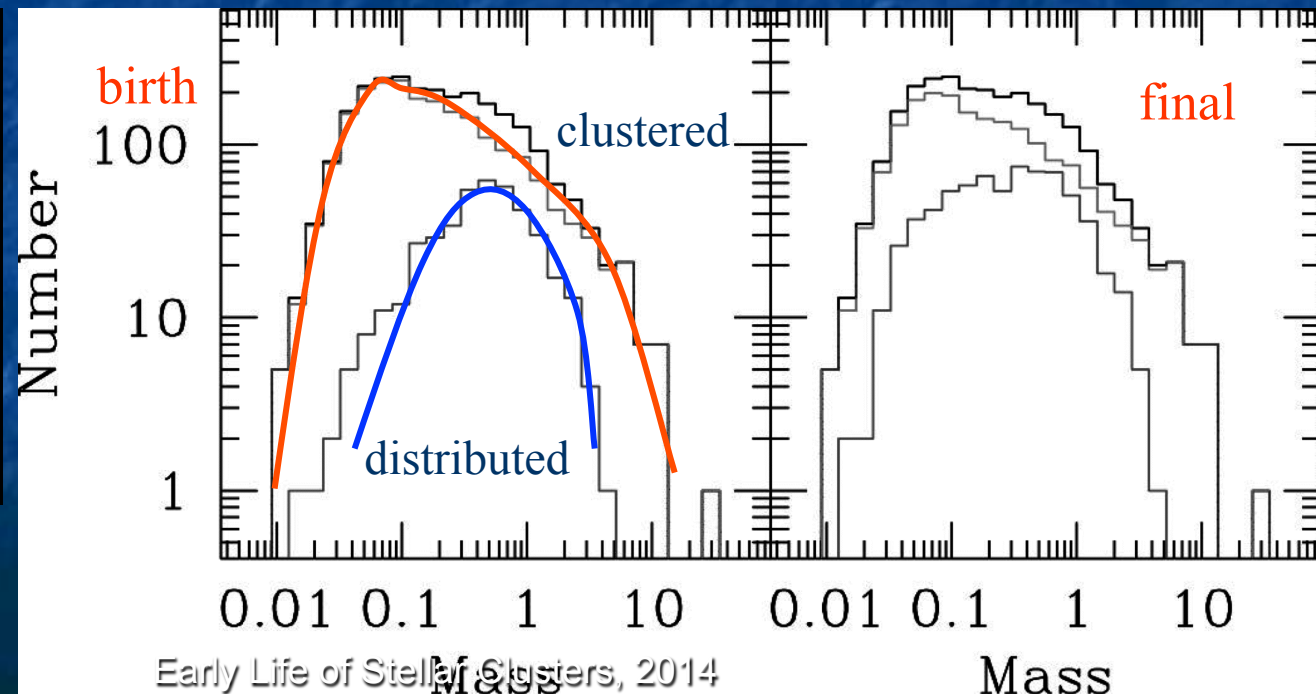

Bonnell et al. 2011

IMF depends on birth environment

- **Stellar clusters**
 - Full IMF
 - Form from **Bound** conditions
 - SFE 20-40 %
- **Distributed SF**
 - No high-mass, few low mass stars
 - Flat/Peaked IMF
 - Unbound regions
 - Low SF efficiencies

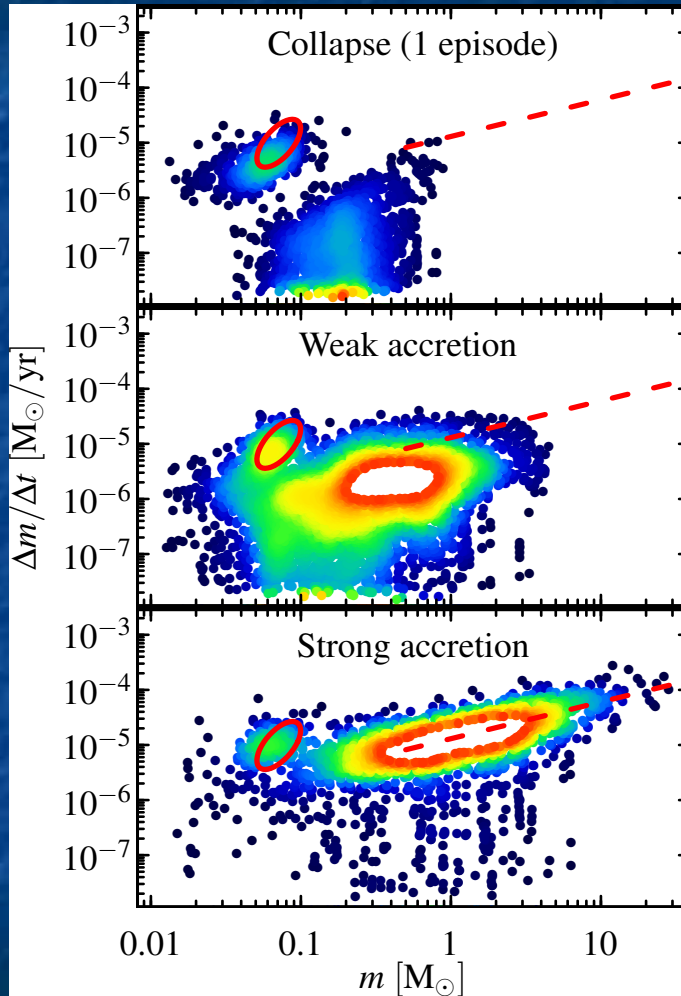

Clark et al 2007; Bonnell et al 2011

Accretion in Clusters

- Higher mass stars formed through accretion

$$\dot{M} \propto M^{2/3}$$

■ Tidal radius accretion

Maschberger et al 2014

University

St Andrews

Formation of stellar clusters

Fragmentation in
filaments

clusters grow at
intersection of filaments

Filaments feed gas and
stars into cluster

Clusters grow through
Hierarchical mergers

~ 2 pc

Bonnell et al 2011

Accretion reservoirs

Accretion onto high-mass stars
comes from cluster scale, lower
density gas

Yellow = mass which will be accreted
by the most massive sink within 0.25
 t_{dyn}

Infalling fragments (cores) form low-
mass stars

Molecular cloud formation

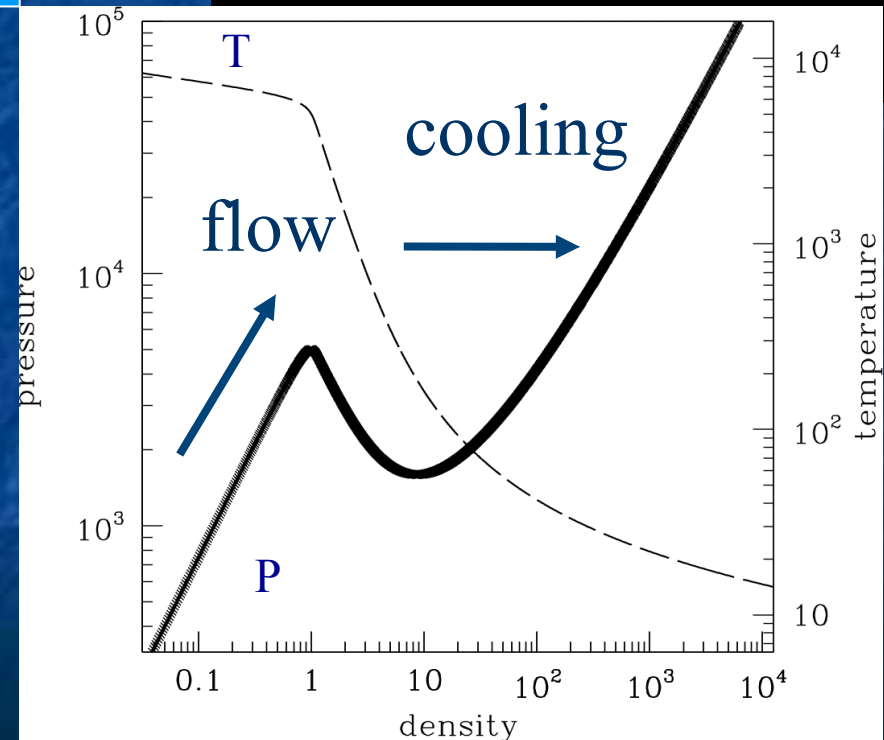

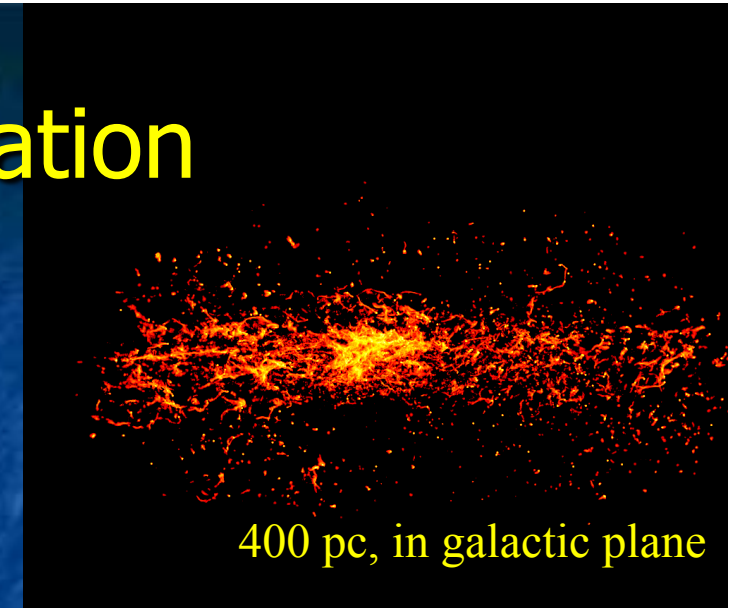

- Clouds formed by shock
- Ram pressure from flow
 - At ~ 30 km/s
- Compresses gas
- Thermal instability and cooling
- **Generate internal turbulence**

$$P_{ram} = \rho v_s^2$$

Bonnell et al 2006; Dobbs & Bonnell 2007
Bonnell, Dobbs & Smith 2013

- Thermal pressure of hot gas

Can form without self-gravity

Galactic triggering of star formation

25 million SPH particles

Cooling curve

Smooth mixture of cold-dense gas and hot gas:

10 to $\sim 10^4$ K

High resolution region 200x200pc

Cold gas $1.7 \times 10^6 M_{\odot}$ gas

Resolution $\sim 10 M_{\odot}$, 0.05 pc

Drives turbulence

Initial Conditions for Star Formation

$\sim 10^6 M_{\odot}$ at molecular cloud densities
in ~ 100 pc, With self-gravity

250 pc, in galactic plane

- **Clouds globally unbound**

- Formed by spiral shock

$$M_{cloud} < M_{vir} < 10 M_{cloud}$$

- Locally: forms bound clumps

- $M \sim 1000 M_{\odot}$; $R \sim$ few pc

highly structured

Cooler inside / warmer outside

University
of
St Andrews

With self-gravity:

European Research Council
Established by the European Commission

Sink particles

0.25 pc

$M > 10 M_{\odot}$

>1000 sinks

not individual
stars

$\sim 10^5 M_{\odot}$
in 5 Myr

~ 100 pc

Star Formation Rates

Local estimates of star formation rates

- After $t=3.5$ Myr
- Grid, sizes of 50×50 pc
- Over 3 simulations with $\Sigma_{\text{gas}} = 0.4, 4$ and $40 M_{\odot} \text{pc}^{-2}$
- S-K power law, but higher, closer to nearby GMC (Heiderman et al 2011)
- **Critical step : formation of dense cold gas**

$$\Sigma_{\text{SFR}} \propto \Sigma_{\text{mol}} \propto \Sigma_{\text{gas}}^{3/2}$$

Upper limits on SFRs:

- Magnetic fields
- Feedback
- Additional turbulence

Star Formation Rates

Surface density of gas

Dense gas: precursor for star formation

- Cold, dense gas follows same relation

$$\Sigma_{cold} \propto \Sigma_{gas}^{3/2}$$

- Even without self-gravity
 - Due to shock and cooling

$$\Sigma_{SFR} \approx \frac{\Sigma_{cold}}{t_{ff}}$$

Where does the star forming gas come from?

- Cool gas, $T < 1000$ K
- Cold gas, $T < 100$ K
 - 10's of Myr
- From previous shocks
- Dense gas
 - $\rho > 10 M_{\text{sun}} \text{ pc}^{-3}$
 - ~ 5 Myr
 - Easier to compress cool gas

Initial conditions for star formation

- Two phases of gas: dense (cold) and less dense (hot)
- Trace star forming gas through evolution
- Star forming gas (coloured) - located in dense gas regions
- Highest density gas undergoes star formation first (blue)

Triggering Star Formation

European Research Council
Established by the European Commission

R. Smilgys

velocities

Colours : Depletion times

Formation of Stellar Clusters

Stellar clusters gather
gas from large distances

Small clusters $< 5-10$ pc
Large clusters
 $\sim 10-100$ pc

What drives star formation ?

Compare theoretical timescales with simulated SF times

- 1) Galactic flows dominate on large scales ($\sim 10+$ pc)
- 2) Self-gravity of forming cluster dominates on smaller scales,
- 3) For Densities $> 10^3 \text{ cm}^{-3}$

Summary

Large-scale Shocks and cooling can trigger star formation

- **Realistic molecular clouds (structures/dynamics)?**
 - Large scale turbulence driving
 - Need not be globally bound : low star formation efficiencies
- Schmidt-Kennicutt type SFR relations (but higher)
- **Clusters form from several to 10's pc scales**
 - Assembled by large scale flows
 - Clusters form in bound regions (global infall)
 - Age spreads up to several Myrs

- **Massive stars accrete as**

$$\dot{M} \propto M^{2/3}$$

- Ionising Feedback factor of 2 decrease n SFR
